multiarch], package size 924 kB, installed size 3536 kB (Only available for any (386, amd64, armel, armhf, i386, mips, mipsel, powerpc, ppc64el, s390x)) 0. What's the most likely cause of this issue, and what is the most appropriate way to fix it? A: Firstly, congrats on using the new KVM. I'm surprised you're able to build and run libvirtd, as there is a recent update to KVM which fixed a bug that caused libvirtd and virsh to segfault when using the qemu.kvm module. As to your specific issue, there was a recent update to KVM (1.1.4.1) which added support for the QEMU\_IMG\_OPT\_FORCE flag. This should resolve your issue and you can verify with virsh qemu-img --help. So, while I cannot explain why the KVM update is giving you the segfault, it would be safe to assume that it is related to your KVM version. It appears the cause is not only related to the fact that you are using the 'legacy' module, but also because you are using the 1.1.4.1 version of KVM. The 1.1.4.2 version fixes the issues with

---

the legacy module. In summary, the version of KVM you are using is the problem, so the bug fix (and 'proper' module) is required for you to be able to use this setup. The only viable solution is to use a version of KVM that supports the legacy module (1.1.2) and be careful not to use the 'up to date' version of the QEMU module (1.1.4.1). To get a working KVM (1.1.2) you should use an earlier version of CentOS: # yum --enablerepo=remi-update\* install kvm-1.1.2-5.el6\_4.1.x86\_64 # yum --enablerepo=remi-update\* install qemu-libvirt-1.1.2-5.el6\_4.1.x86\_64 82157476af
